# 1. Setup

- To print  $n$  decimals: `cout << fixed << setprecision(n);`

## Bash script for compilation and execution

setup/compilation.sh

```
1 co() {
2     g++ -std=c++20 -O2 -Wall -Wextra -Wshadow -Wconversion -o $1 $1.cpp
3 }
4
5 run() {
6     co $1 && ./$1;
7 }
```

## C++ template

setup/template.h

```
1 #include <bits/stdc++.h>
2
3 using namespace std;
4
5 #define endl '\n'
6 #define dbg(x) cout << #x << ": " << x << endl
7 #define sz(x) int((x).size())
8 #define all(v) v.begin(), v.end()
9 #define rall(v) v.rbegin(), v.rend()
10 #define pb push_back
```

```
11 #define mp make_pair
12 #define fi first
13 #define se second
14
15 using ll = long long;
16 const ll INF = 1e18;
17 const ll MOD = 1e9 + 7;
```

# 2. Estructuras de Datos

## 2.1. Prefix Sums

### 2.1.1. 2D Prefix Sums

To process  $Q$  queries for the sum over a subrectangle of a 2D matrix with  $N$  rows and  $M$  columns

$$\text{prefix}[a][b] = \sum_{i=1}^a \sum_{j=1}^b \text{arr}[i][j]$$

This can be calculated as follows for row index  $1 \leq i \leq n$  and column index  $1 \leq j \leq m$ :

$$\text{prefix}[i][j] = \text{prefix}[i-1][j] + \text{prefix}[i][j-1] - \text{prefix}[i-1][j-1] + \text{arr}[i][j]$$

The submatrix sum between rows  $a$  and  $A$  and columns  $b$  and  $B$ , can thus be expressed as follows:

$$\sum_{i=a}^A \sum_{j=b}^B \text{arr}[i][j] = \text{prefix}[A][B] - \text{prefix}[a-1][B] - \text{prefix}[A][b-1] + \text{prefix}[a-1][b-1]$$

## 2.2. Segment tree

### Implementation

TIME

- $O(n)$  for building
- $O(\log n)$  for queries and updates

estructuras/segment-tree.cpp

```
6 int n, t[4*MAXN];
7
8 void build(int a[], int v, int tl, int tr) {
9     if (tl == tr) {
10         t[v] = a[tl];
```

```

11 } else {
12     int tm = (tl + tr) / 2;
13     build(a, v*2, tl, tm);
14     build(a, v*2+1, tm+1, tr);
15     t[v] = t[v*2] + t[v*2+1];
16 }
17 }
18
19 int sum(int v, int tl, int tr, int l, int r) {
20     if (l > r)
21         return 0;
22     if (l == tl && r == tr) {
23         return t[v];
24     }
25     int tm = (tl + tr) / 2;
26     return sum(v*2, tl, tm, l, min(r, tm))
27         + sum(v*2+1, tm+1, tr, max(l, tm+1), r);
28 }
29
30 void update(int v, int tl, int tr, int pos, int new_val) {
31     if (tl == tr) {
32         t[v] = new_val;
33     } else {
34         int tm = (tl + tr) / 2;
35         if (pos <= tm)
36             update(v*2, tl, tm, pos, new_val);
37         else
38             update(v*2+1, tm+1, tr, pos, new_val);
39         t[v] = t[v*2] + t[v*2+1];
40     }
41 }

```

## 3. Ordenamiento y Búsqueda

### 3.1. Two Pointers

Some uses:

**Subarray sum:** Given an array of  $n$  positive integers and a target sum  $x$ , and we want to find a subarray whose sum is  $x$  or report that there is no such subarray.

**2SUM Problem:** Given an array of  $n$  numbers and a target sum  $x$ , find two array values such that their sum is  $x$ , or report that no such values exist.

**Merging two sorted arrays:** Given two arrays, sorted in ascending order combine the elements of these arrays into one big array.

```

1 while i < a.size() || j < b.size():
2     if a[i] < b[j]:
3         c[i + j] = a[i]
4         i++
5     else:
6         c[i + j] = b[j]
7         j++

```

**Number of Smaller:** We have two arrays  $a$  and  $b$ . We want to calculate for each element  $b_j$  how many such  $i$  exist that  $a_i < b_j$ .

```

1 i = 0
2 for j = 0..b.size()-1:
3     while i < a.size() && a[i] < b[j]:
4         i++
5     res[j] = i

```

## 3.2. Binary Search on Monotonic Functions

### Finding The Maximum $x$ Such That $f(x) = \text{true}$

TIME  
 $O(\log n)$

```

ordenamiento_busqueda/last_true.cpp
1 #include <bits/stdc++.h>
2 using namespace std;
3
4 int last_true(int lo, int hi, function<bool(int)> f) {
5     // if none of the values in the range work, return lo - 1
6     lo--;
7     while (lo < hi) {
8         // find the middle of the current range (rounding up)
9         int mid = lo + (hi - lo + 1) / 2;
10        if (f(mid)) {
11            // if mid works, then all numbers smaller than mid also work
12            lo = mid;
13        } else {
14            // if mid does not work, greater values would not work either
15            hi = mid - 1;
16        }
17    }

```

```

18  return lo;
19  }
20
21  int main() {
22      // all numbers satisfy the condition (outputs 10)
23      cout << last_true(2, 10, [](int x) { return true; }) << endl;
24
25      // outputs 5
26      cout << last_true(2, 10, [](int x) { return x * x <= 30; }) << endl;
27
28      // no numbers satisfy the condition (outputs 1)
29      cout << last_true(2, 10, [](int x) { return false; }) << endl;
30  }

```

### Finding The Minimum $x$ Such That $f(x) = \text{true}$

TIME  
 $O(\log n)$

ordenamiento\_busqueda/first\_true.cpp

```

1  #include <bits/stdc++.h>
2  using namespace std;
3
4  int first_true(int lo, int hi, function<bool(int)> f) {
5      hi++;
6      while (lo < hi) {
7          int mid = lo + (hi - lo) / 2;
8          if (f(mid)) {
9              hi = mid;
10             } else {
11                 lo = mid + 1;
12             }
13         }
14         return lo;
15     }
16
17     int main() {
18         // outputs 2
19         cout << first_true(2, 10, [](int x) { return true; }) << endl;
20         // outputs 6
21         cout << first_true(2, 10, [](int x) { return x * x >= 30; }) << endl;
22         // outputs 11
23         cout << first_true(2, 10, [](int x) { return false; }) << endl;
24     }

```

## 4. Teoría de gráficas

### 4.1. Graph Traversal

#### 4.1.1. Floodfill

Flood fill is an algorithm that identifies and labels the connected component that a particular cell belongs to in a multidimensional array.

#### ⚠ Advertencia

Recursive implementations of flood fill sometimes lead to

- Memory limit exceeded if you run the recursive implementation on a really big grid (i.e., running the above code on a  $4000 \times 4000$  grid may exceed 256 MB)
  - Non-recursive implementations generally use less memory than recursive ones.

### Example (recursive implementation)

graficas/floodfill\_recursive.cpp

```

1  const int MAX_N = 1000;
2
3  int grid[MAX_N][MAX_N]; // the grid itself
4  int row_num;
5  int col_num;
6  bool visited[MAX_N][MAX_N]; // keeps track of which nodes have been visited
7  int curr_size = 0; // reset to 0 each time we start a new component
8
9  void floodfill(int r, int c, int color) {
10     if ((r < 0 || r >= row_num || c < 0 || c >= col_num) // if out of bounds
11         || grid[r][c] != color // wrong color
12         || visited[r][c] // already visited this square
13     )
14         return;
15
16     visited[r][c] = true; // mark current square as visited
17     curr_size++; // increment the size for each square we visit
18
19     // recursively call flood fill for neighboring squares
20     floodfill(r, c + 1, color);
21     floodfill(r, c - 1, color);
22     floodfill(r - 1, c, color);
23     floodfill(r + 1, c, color);
24 }

```

```

25
26 int main() {
27     /*
28     * input code and other problem-specific stuff here
29     */
30     for (int i = 0; i < row_num; i++) {
31         for (int j = 0; j < col_num; j++) {
32             if (!visited[i][j]) {
33                 curr_size = 0;
34                 /*
35                 * start a flood fill if the square hasn't already been visited,
36                 * and then store or otherwise use the component size
37                 * for whatever it's needed for
38                 */
39                 floodfill(i, j, grid[i][j]);
40             }
41         }
42     }
43     return 0;
44 }

```

### Example (iterative implementation)

graficas/floodfill\_iterative.cpp

```

1  #include <bits/stdc++.h>
2
3  using namespace std;
4
5  const int MAX_N = 2500;
6  const int R_CHANGE[][0, 1, 0, -1];
7  const int C_CHANGE[][1, 0, -1, 0];
8
9  int row_num;
10 int col_num;
11 string building[MAX_N];
12 bool visited[MAX_N][MAX_N];
13
14 void floodfill(int r, int c) {
15     // Note: you can also use a queue and pop from the front for a BFS-based
16     // approach
17     stack<pair<int, int>> frontier;
18     frontier.push({r, c});
19     while (!frontier.empty()) {

```

```

20     r = frontier.top().first;
21     c = frontier.top().second;
22     frontier.pop();
23
24     if (r < 0 || r >= row_num || c < 0 || c >= col_num || building[r][c] == '#' ||
25         visited[r][c])
26         continue;
27
28     visited[r][c] = true;
29     for (int i = 0; i < 4; i++) {
30         frontier.push({r + R_CHANGE[i], c + C_CHANGE[i]});
31     }
32 }
33 }
34
35 int main() {
36     cin >> row_num >> col_num;
37     for (int i = 0; i < row_num; i++) { cin >> building[i]; }
38
39     int room_num = 0;
40     for (int i = 0; i < row_num; i++) {
41         for (int j = 0; j < col_num; j++) {
42             if (building[i][j] == '.' && !visited[i][j]) {
43                 floodfill(i, j);
44                 room_num++;
45             }
46         }
47     }
48     cout << room_num << endl;
49 }

```

## 4.2. Disjoin Set Union

### Find representative with path compression

TIME  
 $O(\log n)$

graficas/dsu\_size.cpp

```

11 int find(int v) {
12     if (v == parent[v])
13         return v;
14     return parent[v] = find(parent[v]);
15 }

```

## Union by size

TIME

$O(\alpha(m, n))$

graficas/dsu\_size.cpp

```

17 DSU_size(int n) : parent(n), size(n, 1) {
18     for (int i = 0; i < n; i++) { parent[i] = i; }
19 }
20
21 bool unite(int a, int b) {
22     a = find(a);
23     b = find(b);
24
25     if (a == b) return false;
26
27     if (size[a] < size[b])
28         swap(a, b);
29     parent[b] = a;
30     size[a] += size[b];
31
32     return true;
33 }
```

## Union by rank

TIME

$O(\alpha(m, n))$

graficas/dsu\_rank.cpp

```

17 DSU_rank(int n) : parent(n), rank(n, 0) {
18     for (int i = 0; i < n; i++) { parent[i] = i; }
19 }
20
21 bool unite(int a, int b) {
22     a = find(a);
23     b = find(b);
24
25     if (a == b) return false;
26
27     if (rank[a] < rank[b])
28         swap(a, b);
29     parent[b] = a;
30     if (rank[a] == rank[b])
31         rank[a]++;
32 }
```

```

32
33     return true;
34 }
```

## 4.3. Topological Sort

A topological sort of a directed acyclic graph is a linear ordering of its vertices such that for every directed edge  $u \rightarrow v$  from vertex  $u$  to vertex  $v$ ,  $u$  comes before  $v$  in the ordering.

### DFS Version

graficas/topological\_sort\_dfs.cpp

```

1 #include <bits/stdc++.h>
2
3 using namespace std;
4
5 vector<int> top_sort;
6 vector<vector<int>> graph;
7 vector<bool> visited;
8
9 void dfs(int node) {
10     for (int next : graph[node]) {
11         if (!visited[next]) {
12             visited[next] = true;
13             dfs(next);
14         }
15     }
16     top_sort.push_back(node);
17 }
18
19 int main() {
20     int n, m; // The number of nodes and edges respectively
21     cin >> n >> m;
22
23     graph = vector<vector<int>>(n);
24     for (int i = 0; i < m; i++) {
25         int a, b;
26         cin >> a >> b;
27         graph[a - 1].push_back(b - 1);
28     }
29
30     visited = vector<bool>(n);
```

```

31 for (int i = 0; i < n; i++) {
32     if (!visited[i]) {
33         visited[i] = true;
34         dfs(i);
35     }
36 }
37 reverse(top_sort.begin(), top_sort.end());
38
39 vector<int> ind(n);
40 for (int i = 0; i < n; i++) { ind[top_sort[i]] = i; }
41
42 // Check if the topological sort is valid
43 bool valid = true;
44 for (int i = 0; i < n; i++) {
45     for (int j : graph[i]) {
46         if (ind[j] <= ind[i]) {
47             valid = false;
48             goto answer;
49         }
50     }
51 }
52 answer;
53
54 if (valid) {
55     for (int i = 0; i < n - 1; i++) { cout << top_sort[i] + 1 << ' '; }
56     cout << top_sort.back() + 1 << endl;
57 } else {
58     cout << "IMPOSSIBLE" << endl;
59 }
60 }

```

### BFS Version (Kahn's Algorithm)

graficas/topological\_sort\_bfs.cpp

```

1 #include <bits/stdc++.h>
2
3 using namespace std;
4
5 int main() {
6     int n, m;
7     cin >> n >> m;
8
9     vector<vector<int>> graph(n);

```

```

10 for (int i = 0; i < m; i++) {
11     int a, b;
12     cin >> a >> b;
13     graph[a - 1].push_back(b - 1);
14 }
15
16 vector<int> in_degree(n);
17 for (const vector<int> &nodes : graph) {
18     for (int node : nodes) { in_degree[node]++; }
19 }
20
21 queue<int> queue;
22 for (int i = 0; i < n; i++) {
23     if (in_degree[i] == 0) { queue.push(i); }
24 }
25 vector<int> top_sort;
26 while (!queue.empty()) {
27     int curr = queue.front();
28     queue.pop();
29     top_sort.push_back(curr);
30     for (int next : graph[curr]) {
31         if (--in_degree[next] == 0) { queue.push(next); }
32     }
33 }
34
35 if (top_sort.size() == n) {
36     for (int i = 0; i < n - 1; i++) { cout << top_sort[i] + 1 << ' '; }
37     cout << top_sort.back() + 1 << endl;
38 } else {
39     cout << "IMPOSSIBLE" << endl;
40 }
41 }

```

## 5. Programación Dinámica

### Kadane's algorithm

TIME  
 $O(n)$

Given an array of integers, find the maximum sum subarray.

#### dp/kadane.cpp

```
4 long long kadane(vector<long long>& arr) {
5     long long max_ending_here = arr[0];
6     long long max_so_far = arr[0];
7     for (size_t i = 1; i < arr.size(); ++i) {
8         max_ending_here = max(arr[i], max_ending_here + arr[i]);
9         max_so_far = max(max_so_far, max_ending_here);
10    }
11    return max_so_far;
12 }
```

### Knapsack 0/1

TIME  
 $O(nW)$

Given weights and values of  $n$  items, put these items in a knapsack of capacity  $W$  to get the maximum total value in the knapsack.

#### dp/knapsack01.cpp

```
4 int knapsack01(vector<int>& w, vector<int>& v, int W) {
5     int n = w.size();
6     vector<vector<int>> dp(n + 1, vector<int>(W + 1, 0));
7
8
9     for (int i = 1; i <= n; ++i) {
10        for (int j = 0; j <= W; ++j) {
11            dp[i][j] = dp[i-1][j]; // no tomar el objeto i
12            if (w[i-1] <= j)
13                dp[i][j] = max(dp[i][j], dp[i-1][j - w[i-1]] + v[i-1]);
14        }
15    }
16    return dp[n][W];
17 }
```

### Coin Change

#### dp/coin\_change.cpp

```
4 long long coin_change(vector<int>& coins, int X) {
5     vector<long long> dp(X + 1, 0);
6     dp[0] = 1; // una forma de formar 0
7
8     for (int c : coins) {
9         for (int x = c; x <= X; ++x) {
```

```
10        dp[x] = (dp[x] + dp[x - c]) % MOD;
11    }
12 }
13 return dp[X];
14 }
```

## 6. Teoría de números

### 6.1. Cribas

#### Criba de primos con optimizaciones básicas

TIME  
 $O(n \log \log n)$

SPACE  
 $O(n)$

Find all the prime numbers in  $[1, n]$ . This code uses the next optimizations:

- Sieving till root
- Sieving by the odd numbers only

#### teoria\_de\_numeros/sieve\_with\_basic\_optimizations.cpp

```
1 #include <bits/stdc++.h>
2 using namespace std;
3
4 vector<bool> sieve(int n) {
5     vector<bool> is_prime(n + 1, true);
6     is_prime[0] = is_prime[1] = false;
7     for (int i = 3; i * i <= n; i += 2) {
8         if (is_prime[i]) {
9             for (int j = i * i; j <= n; j += 2 * i)
10                is_prime[j] = false;
11        }
12    }
13    return is_prime;
14 }
```

### 6.2. Euclid's Algorithm

The algorithm is based on the formula

$$\gcd(a, b) = \begin{cases} a & b = 0 \\ \gcd(b, a \bmod b) & b \neq 0 \end{cases}$$

### 6.2.1. Extended Euclid's Algorithm:

Euclid's algorithm can also be extended so that it gives integers  $x$  and  $y$  for which

$$ax + by = \gcd(a, b)$$

#### Iterative version

TIME  
 $O(\log \min(a, b))$

teoria\_de\_numeros/extended\_euclid\_algorithm.cpp

```
1 int gcd(int a, int b, int& x, int& y) {
2     x = 1, y = 0;
3     int x1 = 0, y1 = 1, a1 = a, b1 = b;
4     while (b1) {
5         int q = a1 / b1;
6         tie(x, x1) = make_tuple(x1, x - q * x1);
7         tie(y, y1) = make_tuple(y1, y - q * y1);
8         tie(a1, b1) = make_tuple(b1, a1 - q * b1);
9     }
10    return a1;
11 }
```

## 6.3. Euler's Theorem

Euler's totient function  $\varphi(n)$  gives the number of integers between  $1, \dots, n$  that are coprime to  $n$ .

Any value of  $\varphi(n)$  can be calculated from the prime factorization of  $n$  using the formula

$$\varphi(n) = \prod_{i=1}^k p_i^{\alpha_i-1} (p_i - 1)$$

#### Teorema 6.3.1 (Euler's theorem)

For all positive coprime integers  $x$  and  $m$

$$x^{\varphi(m)} \bmod m = 1$$

## 6.4. Solving Equations

We can efficiently solve a Diophantine equation by using the extended Euclid's algorithm which gives integers  $x$  and  $y$  that satisfy the equation

$$ax + by = \gcd(a, b)$$

A Diophantine equation can be solved exactly when  $c$  is divisible by  $\gcd(a, b)$ .

If a pair  $(x, y)$  is a solution, then also all pairs

$$\left(x + \frac{kb}{\gcd(a, b)}, y - \frac{ka}{\gcd(a, b)}\right)$$

are solutions, where  $k$  is any integer.

# 7. Combinatoria

## 7.1. Binomial Coefficients

### Nota

For  $n < k$  the value of  $\binom{n}{k}$  is assumed to be zero.

#### Basic Improved Implementation

```
1 int C(int n, int k) {
2     double res = 1;
3     for (int i = 1; i <= k; ++i)
4         res = res * (n - k + i) / i;
5     return (int)(res + 0.01);
6 }
```

#### Table of binomial coefficients using Pascal's Triangle identity

```
1 const int maxn = ...;
2 int C[maxn + 1][maxn + 1];
3 C[0][0] = 1;
4 for (int n = 1; n <= maxn; ++n) {
5     C[n][0] = C[n][n] = 1;
6     for (int k = 1; k < n; ++k)
7         C[n][k] = C[n - 1][k - 1] + C[n - 1][k];
8 }
```

# 8. Strings

## 8.1. Trie

#### Estructura

strings/trie.cpp

```
4 const int K = 26;
```

```

5
6 struct Vertex {
7     int next[K];
8     bool output = false;
9
10    Vertex() {
11        fill(begin(next), end(next), -1);
12    }
13 };
14
15 vector<Vertex> trie(1);

```

### Agregar una cadena

strings/trie.cpp

```

19 void add_string(string const& s) {
20     int v = 0;
21     for (char ch : s) {
22         int c = ch - 'a';
23         if (trie[v].next[c] == -1) {
24             trie[v].next[c] = trie.size();
25             trie.emplace_back();
26         }
27         v = trie[v].next[c];
28     }
29     trie[v].output = true;
30 }

```

### hash-doble

strings/Hash\_Doble.cpp

```

3 struct Hash { //doble hashing
4     vector<ll> h1, h2;
5     vector<ll> p1, p2;
6     ll p=31; //tomamos esta p para evitar colisiones
7     Hash(string &s) {
8         int n = s.size();
9         h1.resize(n+1, 0);
10        h2.resize(n+1, 0);
11        p1.resize(n+1, 1);
12        p2.resize(n+1, 1);
13        //hacemos doble hasheo para evitar colisiones
14        for (int i = 0; i < n; i++) {

```

```

15        p1[i+1] = (p1[i] * p) % MOD; //a uno le aplicamos modulo
16        p2[i+1] = (p2[i] * p); //el otro ocupamos el modulo implicito de ll
17        //uno con mod 10e9+7 y otro con 2e64 que es LLONG_MAX
18        int val = s[i] - 'a' + 1; //hasheamos con el ascii
19
20        h1[i+1] = (h1[i] * p + val) % MOD;
21        h2[i+1] = (h2[i] * p + val);
22    }
23 }
24
25 pair<ll, ll> get(ll l, ll r) { //comparamos los 2 hashing
26     ll x1 = (h1[r+1] - h1[l] * p1[r-l+1] % MOD + MOD) % MOD;
27     ll x2 = (h2[r+1] - h2[l] * p2[r-l+1]);
28     return {x1, x2};
29 }
30 };
31 Hash hs(s); //inicializar
32 hs.get(i, j); //lugar de sonde se compara
33 if(hs.get(l, m) == hs.get(i, j)) //si 2 cadenas son iguales

```

### KMP — Knuth-Morris-Pratt

TIME

$O(n + m)$

SPACE

$O(m)$

Cuenta ocurrencias de pat en txt. buildPhi construye el arreglo de fallos: phi[j] = prefijo propio más largo de pat[0..j] que es sufijo. Al fallar retrocede a phi[i-1] en lugar de reiniciar.

strings/kmp.cpp

```

5 // snippet: kmp
6 vll buildPhi(const vll& pat) {
7     ll m = pat.size();
8     vll phi(m, 0);
9     for (ll j = 1, i = 0; j < m; j++) {
10         while (i > 0 && pat[i] != pat[j]) i = phi[i - 1];
11         if (pat[i] == pat[j]) i++;
12         phi[j] = i;
13     }
14     return phi;
15 }
16
17 ll KMP(const vll& pat, const vll& txt) {
18     ll m = pat.size(), n = txt.size();

```

```

19  if (m == 0) return 0;
20  vll phi = buildPhi(pat);
21  ll matches = 0;
22  for (ll i = 0, j = 0; j < n; j++) {
23      while (i > 0 && pat[i] != txt[j]) i = phi[i - 1];
24      if (pat[i] == txt[j]) i++;
25      if (i == m) { matches++; i = phi[i - 1]; }
26  }
27  return matches;
28 }
29 // snippet: end

```

## 9. Manipulación de bits

### 9.1. Máscara de bits

#### 9.1.1. Manipulación individual de bits

Establece en 1 el  $k$ -ésimo bit de  $x$ :

```
1 #define ON(x, k) ((x) | (1LL << (k)))
```

Establece en 0 el  $k$ -ésimo bit de  $x$ :

```
1 #define OFF(x, k) ((x) & ~(1LL << (k)))
```

Invierte el  $k$ -ésimo bit de  $x$ :

```
1 #define TOGGLE(x, k) ((x) ^ (1LL << (k)))
```

Comprueba si el  $k$ -ésimo bit de  $x$  es 1:

```
1 #define CHECK(x, k) ((x) & (1LL << (k)))
```

#### 9.1.2. Working with the rightmost 1-bit

$x$  &  $-x$ : Isolates the rightmost set bit (keeps only the least significant bit that is 1, sets all others to 0).

$x$  &  $(x - 1)$ : Removes the rightmost set bit from  $x$  (turns the rightmost 1 to 0).

$x | (x - 1)$ : Sets all trailing zeros of  $x$  to 1.

#### 9.1.3. Creating useful bit masks

$(1 << n) - 1$ : Creates a bit mask with the first  $n$  bits set to 1.

#### 9.1.4. Common bit manipulation tricks

- A positive number  $x$  is a power of two exactly when  $x \& (x - 1) = 0$ .

$x \wedge A \wedge B$ : Determines which is not the current value of  $x$  between  $A$  and  $B$ .

#### 9.1.5. Bit operations as math alternatives

$x \ll k$ : equivalent to  $x * \text{pow}(2, k)$

$x \gg k$ : equivalent to  $x / \text{pow}(2, k)$  (integer division)

$x \& ((1 \ll k) - 1)$ : equivalent to  $x \% \text{pow}(2, k)$

$A + B$ : equivalent to  $(A \wedge B) + 2 * (A \& B)$  or  $(A | B) + (A \& B)$

#### 9.1.6. GNU C++ compiler built-in functions

`__builtin_clz(x)`: the number of leading zeros (zeros on the left side of the bit representation).

`__builtin_ctz(x)`: the number of trailing zeros (zeros on the right side of the bit representation).

`__builtin_popcount(x)`: the number of ones in the bit representation.

`__builtin_parity(x)`: the parity (even or odd) of the number of ones in the bit representation.

| Example of use                                                         |
|------------------------------------------------------------------------|
| 1 <code>int x = 5328; // 000000000000000000001010011010000</code>      |
| 2 <code>cout &lt;&lt; __builtin_clz(x) &lt;&lt; "\n"; // 19</code>     |
| 3 <code>cout &lt;&lt; __builtin_ctz(x) &lt;&lt; "\n"; // 4</code>      |
| 4 <code>cout &lt;&lt; __builtin_popcount(x) &lt;&lt; "\n"; // 5</code> |
| 5 <code>cout &lt;&lt; __builtin_parity(x) &lt;&lt; "\n"; // 1</code>   |

#### Nota

The above functions only support `int` numbers, but there are also `long long` versions of the functions available with the suffix `ll` (e.g. `__builtin_popcountll(x)`).

## 9.2. Representing Sets

Every subset of a set  $\{0, 1, 2, \dots, n - 1\}$  can be represented as an  $n$  bit integer whose one bits indicate which elements belong to the subset.

| Goes through the subsets with exactly $k$ elements           |
|--------------------------------------------------------------|
| 1 <code>for (int b = 0; b &lt; (1 &lt;&lt; n); b++) {</code> |
| 2 <code>if (__builtin_popcount(b) == k) {</code>             |
| 3 <code>// process subset b</code>                           |
| 4 <code>}</code>                                             |
| 5 <code>}</code>                                             |

#### Goes through the subsets of a set x

```
1 int b = 0;
2 do {
3     // process subset b
4 } while (b=(b-x)&x);
```

The idea is that the formula  $b - x$  detects the rightmost one bit in  $x$  that is zero in  $b$ . This bit becomes one and all bits after it become zero. Then the and operation ensures that the resulting value is a subset of  $x$ . Note that  $b - x$  equals  $-(x - b)$  so we can think that we first remove all one bits that appear in  $b$  and then invert the value and add one.

## 9.3. Bitsets

The bitset structure corresponds to an array whose each value is either 0 or 1.

#### Creates a bitset of 10 elements

```
1 bitset<10> s;
2 s[1] = 1;
3 s[3] = 1;
4 s[4] = 1;
5 s[7] = 1;
6 cout << s[4] << "\n"; // 1
7 cout << s[5] << "\n"; // 0
```

#### Returns the number of one bits in the bitset

```
1 cout << s.count() << "\n"; // 4
```

#### Bit operations can be directly used to manipulate bitsets

```
1 bitset<10> a, b;
2 // ...
3 bitset<10> c = a&b;
4 bitset<10> d = a|b;
5 bitset<10> e = a^b;
```

#### Recorrer bitset

```
1 for (int i = 0; i < (int)bs.size(); ++i) {
2     cout << "bit " << i << ": " << bs[i] << "\n";
3 }
```

#### Mostrar máscara como binario

```
1 cout << "maskNum = " << bitset<8>(maskNum) << "\n";
```

# 10. Definiciones y resultados útiles

## 10.1. Teoría de números

### 10.1.1. Primos

- Primeros 50 números primos:

2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, 127, 131, 137, 139, 149, 151, 157, 163, 167, 173, 179, 181, 191, 193, 197, 199, 211, 223, 227, 229

- Para todo entero  $n > 1$ , existe una factorización prima única

$$n = p_1^{\alpha_1} p_2^{\alpha_2} \cdots p_k^{\alpha_k}$$

- La función contadora de primos  $\pi(n)$  da el número de primos hasta  $n$ :

$$\pi(n) \approx \frac{n}{\ln(n)}$$

- Número de divisores de un entero  $n$ :

$$\tau(n) = \prod_{i=1}^k (\alpha_i + 1)$$

- Suma de divisores de un entero  $n$ :

$$\sigma(n) = \prod_{i=1}^k (1 + p_i + \dots + p_i^{\alpha_i}) = \prod_{i=1}^k \frac{p_i^{\alpha_i+1} - 1}{p_i - 1}$$

### 10.1.2. Aritmética modular

#### Definición 10.1.1 (Modular multiplicative inverse)

The modular multiplicative inverse of  $x$  with respect to  $m$  is a value  $\text{inv}_m(x)$  such that

$$x \cdot \text{inv}_m(x) \bmod m = 1$$

If  $m$  is prime

$$\text{inv}_m(x) = x^{m-2}$$

- Factorial inverso modular:

$$\text{inv}_p((x-1)!) \equiv x * \text{inv}_p((x!)) \bmod p$$

## 10.2. Combinatoria

### 10.2.1. Números de Fibonacci

$$F_0 = 0, F_1 = 1, F_n = F_{n-1} + F_{n-2}$$

- Primeros 30 términos:  
0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597, 2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418, 317811, 514229

### 10.2.2. Coeficientes binomiales

- Pascal's Triangle:

$$\binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k}$$

- Symmetry rule:

$$\binom{n}{k} = \binom{n}{n-k}$$

- Factoring in:

$$\binom{n}{k} = \frac{n}{k} \binom{n-1}{k-1}$$

- Sum over  $k$ :

$$\sum_{k=0}^n \binom{n}{k} = 2^n$$

- Sum over  $n$ :

$$\sum_{m=0}^n \binom{m}{k} = \binom{n+1}{k+1}$$

- Sum over  $n$  and  $k$ :

$$\sum_{k=0}^m \binom{n+k}{k} = \binom{n+m+1}{m}$$

- Sum of the squares:

$$\binom{n}{0}^2 + \binom{n}{1}^2 + \cdots + \binom{n}{n}^2 = \binom{2n}{n}$$

- Weighted sum:

$$1\binom{n}{1} + 2\binom{n}{2} + \cdots + n\binom{n}{n} = n2^{n-1}$$

- Connection with the Fibonacci numbers:

$$\binom{n}{0} + \binom{n-1}{1} + \cdots + \binom{n-k}{k} + \cdots + \binom{0}{n} = F_{n+1}$$

### 10.2.3. Desarreglos

# 11. Utilidades

## 11.1. Strings

| Method/Syntax                             | Description                                 | Complexity            | Example                                    |
|-------------------------------------------|---------------------------------------------|-----------------------|--------------------------------------------|
| <code>s.insert(pos, str)</code>           | Inserts string at position                  | $O(n+m)$              | <code>s.insert(2, "abc");</code>           |

| <code>s.find_last_of(chars)</code>        | Finds last occurrence of any char in chars  | $O(n*m)$              | <code>s.find_last_of("aeiou");</code>      |
| <code>s.find_first_not_of(chars)</code>   | Finds first char not in chars               | $O(n*m)$              | <code>s.find_first_not_of(" \t");</code>   |
| <code>s.find_last_not_of(chars)</code>    | Finds last char not in chars                | $O(n*m)$              | <code>s.find_last_not_of(" \t");</code>    |
| <code>s.replace(pos, len, str)</code>     | Replaces len chars at pos with str          | $O(n+m)$              | <code>s.replace(2, 3, "xyz");</code>       |
| <code>s.compare(str)</code>               | Lexicographically compares strings          | $O(\min(n,m))$        | <code>int cmp = s.compare("abc");</code>   |
| <code>s.c_str()</code>                    | Returns C-style null-terminated string      | $O(1)$                | <code>const char* cstr = s.c_str();</code> |
| <code>s.data()</code>                     | Returns pointer to character array          | $O(1)$                | <code>char* ptr = s.data();</code>         |
| <code>s.reserve(n)</code>                 | Reserves capacity for n characters          | $O(1)$                | <code>s.reserve(1000);</code>              |
| <code>s.resize(n, c)</code>               | Changes size to n, filling with c if needed | $O(n)$                | <code>s.resize(10, 'x');</code>            |
| <code>s.clear()</code>                    | Removes all characters                      | $O(n)$                | <code>s.clear();</code>                    |
| <code>s.swap(other)</code>                | Swaps contents with another string          | $O(1)$                | <code>s.swap(t);</code>                    |
| <code>getline(cin, s)</code>              | Reads entire line including spaces          | $O(n)$                | <code>getline(cin, s);</code>              |
| <code>getline(cin, s, delim)</code>       | Reads until delimiter character             | $O(n)$                | <code>getline(cin, s, ',');</code>         |
| <code>stoi(s) / stol(s) / stoll(s)</code> | Converts string to int/long/long long       | $O(n)$                | <code>int num = stoi("123");</code>        |
| <code>stof(s) / stod(s)</code>            | Converts string to float/double             | $O(n)$                | <code>double d = stod("3.14");</code>      |
| <code>to_string(num)</code>               | Converts number to string                   | $O(\log \text{ num})$ | <code>string s = to_string(42);</code>     |
| <code>isalpha(c) / isdigit(c)</code>      | Checks if char is letter/digit              | $O(1)$                | <code>if (isalpha(s[i])) { ... }</code>    |
| <code>islower(c) / isupper(c)</code>      | Checks if char is lowercase/uppercase       | $O(1)$                | <code>if (islower(s[i])) { ... }</code>    |
| <code>tolower(c) / toupper(c)</code>      | Converts char to lowercase/uppercase        | $O(1)$                | <code>s[i] = tolower(s[i]);</code>         |
| <code>isspace(c)</code>                   | Checks if char is whitespace                | $O(1)$                | <code>if (isspace(s[i])) { ... }</code>    |
| <code>isalnum(c)</code>                   | Checks if char is alphanumeric              | $O(1)$                | <code>if (isalnum(s[i])) { ... }</code>    |

### 11.1.1. Important Notes:

- **String indexing:** Use `s[i]` for fast access, `s.at(i)` for bounds checking

- **Find functions:** Return `string::npos` if not found (usually `-1` or large value)
- **Character functions:** `isalpha`, `isdigit`, etc. are in `<cctype>` header
- **Conversion functions:** `stoi`, `to_string`, etc. are in `<string>` header
- **Amortized complexity:** `push_back` is  $O(1)$  on average due to capacity doubling

### 11.1.2. Useful Patterns:

```

1  // Check if substring exists
2  if (s.find("pattern") != string::npos) { ... }
3
4  // Convert string to lowercase
5  transform(s.begin(), s.end(), s.begin(), [](char c) { return tolower(c); });
6
7  // Split string by delimiter
8  stringstream ss(s); string token;
9  while (getline(ss, token, ',')) { ... }
10
11 // Remove leading/trailing whitespace
12 s.erase(0, s.find_first_not_of(" \t"));
13 s.erase(s.find_last_not_of(" \t") + 1);
14
15 // Reverse string
16 reverse(s.begin(), s.end());

```

## 11.2. STL Algorithm

| Function/Syntax                             | Description                                          | Complexity    | Example                                           |
|---------------------------------------------|------------------------------------------------------|---------------|---------------------------------------------------|
| <code>sort(begin, end)</code>               | Sorts elements in ascending order                    | $O(n \log n)$ | <code>sort(v.begin(), v.end())</code>             |
| <code>stable_sort(begin, end)</code>        | Sorts maintaining relative order of equal elements   | $O(n \log n)$ | <code>stable_sort(v.begin(), v.end())</code>      |
| <code>reverse(begin, end)</code>            | Reverses the order of elements                       | $O(n)$        | <code>reverse(v.begin(), v.end())</code>          |
| <code>binary_search(begin, end, val)</code> | Searches for value in sorted range (returns bool)    | $O(\log n)$   | <code>binary_search(v.begin(), v.end(), x)</code> |
| <code>lower_bound(begin, end, val)</code>   | Finds first element $\geq$ val                       | $O(\log n)$   | <code>lower_bound(v.begin(), v.end(), x)</code>   |
| <code>upper_bound(begin, end, val)</code>   | Finds first element $>$ val                          | $O(\log n)$   | <code>upper_bound(v.begin(), v.end(), x)</code>   |
| <code>equal_range(begin, end, val)</code>   | Returns pair of iterators [lower_bound, upper_bound] | $O(\log n)$   | <code>equal_range(v.begin(), v.end(), x)</code>   |
| <code>min_element(begin, end)</code>        | Finds iterator to minimum element                    | $O(n)$        | <code>min_element(v.begin(), v.end())</code>      |
| <code>max_element(begin, end)</code>        | Finds iterator to maximum element                    | $O(n)$        | <code>max_element(v.begin(), v.end())</code>      |
| <code>minmax_element(begin, end)</code>     | Returns pair {min_iter, max_iter}                    | $O(n)$        | <code>minmax_element(v.begin(), v.end())</code>   |
| <code>next_permutation(begin, end)</code>   | Generates next lexicographic permutation             | $O(n)$        | <code>next_permutation(v.begin(), v.end())</code> |
| <code>prev_permutation(begin, end)</code>   | Generates previous lexicographic permutation         | $O(n)$        | <code>prev_permutation(v.begin(), v.end())</code> |
| <code>unique(begin, end)</code>             | Removes consecutive duplicate elements               | $O(n)$        | <code>unique(v.begin(), v.end())</code>           |

|                                                                |                                                        |               |                                                                                  |
|----------------------------------------------------------------|--------------------------------------------------------|---------------|----------------------------------------------------------------------------------|
| <code>count(begin, end, val)</code>                            | Counts occurrences of a value                          | $O(n)$        | <code>count(v.begin(), v.end(), x)</code>                                        |
| <code>count_if(begin, end, pred)</code>                        | Counts elements satisfying condition                   | $O(n)$        | <code>count_if(v.begin(), v.end(), [](int x){return x%2==0;})</code>             |
| <code>find(begin, end, val)</code>                             | Finds first occurrence of value                        | $O(n)$        | <code>find(v.begin(), v.end(), x)</code>                                         |
| <code>find_if(begin, end, pred)</code>                         | Finds first element satisfying condition               | $O(n)$        | <code>find_if(v.begin(), v.end(), [](int x){return x&gt;5;})</code>              |
| <code>rotate(begin, middle, end)</code>                        | Rotates elements (middle becomes new begin)            | $O(n)$        | <code>rotate(v.begin(), v.begin()+k, v.end())</code>                             |
| <code>random_shuffle(begin, end)</code>                        | Shuffles elements randomly                             | $O(n)$        | <code>random_shuffle(v.begin(), v.end())</code>                                  |
| <code>shuffle(begin, end, rng)</code>                          | Shuffles with specific random generator                | $O(n)$        | <code>shuffle(v.begin(), v.end(), rng)</code>                                    |
| <code>fill(begin, end, val)</code>                             | Fills range with a value                               | $O(n)$        | <code>fill(v.begin(), v.end(), 0)</code>                                         |
| <code>iota(begin, end, val)</code>                             | Fills with consecutive values starting from val        | $O(n)$        | <code>iota(v.begin(), v.end(), 1)</code>                                         |
| <code>accumulate(begin, end, init)</code>                      | Sums elements (requires <code>&lt;numeric&gt;</code> ) | $O(n)$        | <code>accumulate(v.begin(), v.end(), 0)</code>                                   |
| <code>partial_sum(begin, end, out)</code>                      | Calculates partial sums                                | $O(n)$        | <code>partial_sum(v.begin(), v.end(), prefix.begin())</code>                     |
| <code>merge(begin1, end1, begin2, end2, out)</code>            | Merges two sorted ranges                               | $O(n+m)$      | <code>merge(a.begin(), a.end(), b.begin(), b.end(), c.begin())</code>            |
| <code>inplace_merge(begin, middle, end)</code>                 | Merges two sorted parts of same range                  | $O(n \log n)$ | <code>inplace_merge(v.begin(), v.begin()+k, v.end())</code>                      |
| <code>set_union(begin1, end1, begin2, end2, out)</code>        | Union of two sorted sets                               | $O(n+m)$      | <code>set_union(a.begin(), a.end(), b.begin(), b.end(), c.begin())</code>        |
| <code>set_intersection(begin1, end1, begin2, end2, out)</code> | Intersection of two sorted sets                        | $O(n+m)$      | <code>set_intersection(a.begin(), a.end(), b.begin(), b.end(), c.begin())</code> |
| <code>set_difference(begin1, end1, begin2, end2, out)</code>   | Difference of two sorted sets                          | $O(n+m)$      | <code>set_difference(a.begin(), a.end(), b.begin(), b.end(), c.begin())</code>   |
| <code>nth_element(begin, nth, end)</code>                      | Partitions so nth element is in correct position       | $O(n)$ avg    | <code>nth_element(v.begin(), v.begin()+k, v.end())</code>                        |
| <code>partition(begin, end, pred)</code>                       | Partitions elements by predicate                       | $O(n)$        | <code>partition(v.begin(), v.end(), [](int x){return x%2==0;})</code>            |
| <code>is_sorted(begin, end)</code>                             | Checks if range is sorted                              | $O(n)$        | <code>is_sorted(v.begin(), v.end())</code>                                       |
| <code>is_permutation(begin1, end1, begin2)</code>              | Checks if one range is permutation of another          | $O(n^2)$      | <code>is_permutation(a.begin(), a.end(), b.begin())</code>                       |

### 11.2.1. Important Notes:

- **Sorted ranges required:** `binary_search`, `lower_bound`, `upper_bound`, `equal_range`, `merge`, `set_*` require sorted ranges
- **<numeric> functions:** `accumulate`, `partial_sum`, `iota` are in `<numeric>`, not `<algorithm>`
- **Iterators:** Many functions return iterators. To get indices: `distance(v.begin(), iter)`
- **Predicates:** Functions like `count_if`, `find_if` accept lambdas or functors
- **Custom comparators:** Most accept custom comparators as third parameter

### 11.2.2. Useful Combinations:

```

1 // Sort and remove duplicates
2 sort(v.begin(), v.end());
3 v.erase(unique(v.begin(), v.end()), v.end());

```

## 11.3. STL containers

### 11.3.1. Deques

A *deque* is a dynamic array that can be efficiently manipulated at both ends of the structure.

```
1 deque<int> d;
2 d.push_back(5); // [5]
3 d.push_back(2); // [5,2]
4 d.push_front(3); // [3,5,2]
5 d.pop_back(); // [3,5]
6 d.pop_front(); // [5]
```

The operations of a deque also work in  $O(1)$  average time. Deques should be used only if there is a need to manipulate both ends of the array.

### 11.3.2. Set Structures

The basic operations of sets are element insertion, search and removal. Sets are implemented so that all the above operations are efficient.

#### 11.3.2.1. Sets and Multisets

##### Basic functions

- `insert` adds an element to the set
- `count` returns the number of occurrences of an element in the set
- `erase` removes an element from the set
- `find(x)` returns an iterator that points to an element whose value is  $x$ . However, if the set does not contain  $x$ , the iterator will be `end()`.

##### Prints the number of elements in a set

```
1 cout << s.size() << "\n";
2 for (auto x : s) {
3     cout << x << "\n";
4 }
```

##### Use of find

```
1 auto it = s.find(x);
2 if (it == s.end()) {
3     // x is not found
4 }
```

**Multisets:** A *multiset* is a set that can have several copies of the same value. C++ has the structures `multiset` and `unordered_multiset`.

```
1 multiset<int> s;
2 s.insert(5);
3 s.insert(5);
4 s.insert(5);
5 cout << s.count(5) << "\n"; // 3
```

The function `erase` removes all copies of a value from a multiset:

```
1 s.erase(5);
2 cout << s.count(5) << "\n"; // 0
```

Often, only one value should be removed, which can be done as follows:

```
1 s.erase(s.find(5));
2 cout << s.count(5) << "\n"; // 2
```

Note that the functions `count` and `erase` have an additional  $O(k)$  factor where  $k$  is the number of elements counted/removed. In particular, it is *not* efficient to count the number of copies of a value in a multiset using the `count` function.

### 11.3.3. Priority Queues

Insertion and removal take  $O(\log n)$  time, and retrieval takes  $O(1)$  time.

If we only need to efficiently find minimum or maximum elements, it is a good idea to use a priority queue instead of a set or multiset.

By default, the elements in a C++ priority queue are sorted in decreasing order, and it is possible to find and remove the largest element in the queue.

```
1 priority_queue<int> q;
2 q.push(3);
3 q.push(5);
4 q.push(7);
5 q.push(2);
6 cout << q.top() << "\n"; // 7
7 q.pop();
8 cout << q.top() << "\n"; // 5
9 q.pop();
10 q.push(6);
11 cout << q.top() << "\n"; // 6
12 q.pop();
```

If we want to create a priority queue that supports finding and removing the smallest element, we can do it as follows:

```
1 priority_queue<int, vector<int>, greater<int>> q;
```

### 11.3.4. Policy-based data structures

The g++ compiler also supports some data structures that are not part of the C++ standard library. Such structures are called policy-based data structures. To use these structures, the following lines must be added to the code:

```
1 #include <ext/pb_ds/assoc_container.hpp>
2 using namespace __gnu_pbds;
```

After this, we can define a data structure `indexed_set` that is like `set` but can be indexed like an array. The definition for `int` values is as follows:

```
1 using indexed_set = tree<
2     int,
3     null_type,
```

```
4  less<int>,
5  rb_tree_tag,
6  tree_order_statistics_node_update
7  >;
```

This data structure supports all the operations as a set in C++ in addition to the following:

- `find_by_order(k)`: returns an iterator to the  $k$ -th smallest element (0-based indexing)
- `order_of_key(x)`: returns the number of elements in the set that are strictly less than  $x$
